AI Code Assistants are tools that use AI models to support software development. They include conversational assistants, tools integrated into code editors, and coding agents—for example, GitHub Copilot, ChatGPT, Claude Code and Codex. Depending on the tool and its configuration, they can suggest or generate code, explain codebases, assist with debugging and refactoring, create tests and documentation, or carry out tasks across multiple files. Some provide suggestions for a developer to apply; others can edit files, run commands and tests, and iterate on results within granted permissions.

These tools aim to reduce effort and support productivity, software quality and learning. Their effects depend on how they are used, the tasks they perform, the data and resources they require, and the human review involved. In this workshop, we examine their possible benefits, harms and longer-term consequences across the five sustainability dimensions.
